**Topic Expert Group:** Medical care and clinical practice

**Neonatal jaundice**

**Target group**
Newborn infants and parents

**User group**
Healthcare professionals, neonatal units, hospital, and health service

**Statement of standard**
All newborn infants are assessed for neonatal jaundice with the aim of implementing effective prevention of severe hyperbilirubinaemia.

**Rationale**
Hyperbilirubinaemia is common in newborn infants. Physiological jaundice appears after the first 24 hours of life and usually resolves spontaneously within the first week. However, neonatal hyperbilirubinaemia may also become more severe and require treatment to prevent or treat bilirubin encephalopathy and risk of later cerebral palsy and hearing deficiencies. Monitoring of bilirubin levels in all newborn infants, and awareness of risk factors, are vital for adequate management. Risk factors for severe neonatal hyperbilirubinaemia include: prematurity, haemolytic disorders, early jaundice (<24 hours), bruising and haematoma after delivery, infections, excessive weight loss, family history of jaundice – including conditions such as spherocytosis, conjugation disorders, and haemoglobinopathies, for example sickle cell anaemia and glucose-6-phosphate dehydrogenase deficiency (G6PD), which are more prevalent in Mediterranean, African and Asian populations. (1–3)

Phototherapy is effective in reducing bilirubin concentrations. Initiation of phototherapy should take into account the gestational age, postnatal age and risk factors. Phototherapy usually may be implemented without separating mother and infant. Severe hyperbilirubinaemia may be treated effectively by blood exchange transfusion and the use of gammaglobulin may reduce the need for exchange transfusion in the presence of ongoing haemolysis. (4,5)

In most European countries, national professional societies and health services have developed comprehensive guidelines and charts for the management of hyperbilirubinaemia in their populations, which should be followed. (6–12) It is also critical to monitor for prolonged jaundice (greater than 14 days) in newborn infants and investigation should detect the presence of conjugated hyperbilirubinaemia in such infants. (4,13,14)

**Benefits**

**Short-term benefits**
- Reduced occurrence of severe neonatal jaundice (4,15,16)
- Reduced length of hospital/NICU stay (5)
• Early detection of cholestasis (17)

**Long-term benefits**
• Reduced neurological complications (16)
• Reduced occurrence of hearing loss (16)
• Reduced hospital readmission (17)

**Components of the standard**

**Getting started**

**Initial steps**

For parents and family  
• Parents are verbally informed by healthcare professionals about identification, prevention, and management of hyperbilirubinaemia.

For healthcare professionals  
• Attend training in the management of hyperbilirubinaemia.

For neonatal unit  
• Use published guidelines regarding management of hyperbilirubinaemia including management after discharge. (17)  
• Develop and implement a unit guideline on hyperbilirubinaemia including management after discharge.  
• Develop information material about identification, prevention, and management of hyperbilirubinaemia for parents.

For hospital
• Support healthcare professionals to participate in training in the management of hyperbilirubinemia.
• Provide equipment for non-invasive measurement of bilirubin.

For health service

• Develop and implement a national guideline on hyperbilirubinemia including management after discharge.
